The plates for the intra-mercurial planet search recorded more than 300 stars, including some of the ninth magnitude. All were identified as well-known stars. It is felt that the Lick Observatory observations of 1901, 1905 and 1908 bring definitely to a conclusion the observational side of this problem, famous for half a century. It is not contended that no planets exist in the intra-mercurial region, but it is believed that undiscovered planets do not exist in sufficient numbers to provide the mass necessary to explain the anomalies in the motion of Mercury and the other minor planets.

Value of the Solar Parallax from Photographs of Eros taken in 1900 with the Crosley Reflector: C. D. PERRINE.

The following determination of the values of the solar parallax is based on 823 images of Eros and the images of surrounding groups of stars contained on 281 photographs. These photographs were secured on eighteen nights from October 6 to December 24 inclusive.

The value of the solar parallax obtained is

$$8''.8054 \pm 0''.0025.$$

The measurements and reductions were made under a grant from the Carnegie Institution by Mrs. Moore and Miss Hobe.

The general results will be published in a Lick Observatory Bulletin, and a full account of the work by the Carnegie Institution.
